Code for C++ delete singleton instance

October 26, 2014 by Rakesh Singh

(Last Updated On: August 21, 2020)

Answer: To delete singleton instance or object in C++ programs, we need to follow a proper design to delete singleton object in the class. Especially, when multiple users are using object of [singleton class in C++ program](#). One of the bad situations we can think that what if one user has deleted singleton object while other multiple users are still using the single instance.

So, one of the designs we can follow is “Reference counting” mechanism to delete singleton instance of a class in C++ program. Whenever, a user requests an instance to single class, we can increase the reference count and when he delete it we can decrease the reference count.

Voli Delhi - Milano

€469

ULTE

And deletion of singleton class object would be allow only when the count is zero.

To design C++ delete singleton instance, first, we need to make the singleton class destructor private, so, it can not be accessed from outside of the class. Hence, user cannot delete the singleton instance using the keyword “**delete**”. Also, we have to introduce a static method in the singleton class, say

“releaseInstance() that will be used to delete singleton class pointer.

Introduce a new static variable “count” that will be used to track users. And, also, have two other private method “addRef()” and “releasRef()” to increase and decrease counts of the instance.

Whenever, releaseInstance() function is called, this function will check if singleton class object destruction is required or not.

C++ delete singleton instance design

C++ Code Example

Arraylist Of Objects In

Java
Sum of elements in an array in Java

```

class Singleton{
public:
    static Singleton* GetInstance()
    {
        if(NULL == s_instance)
        {
            s_instance=new
Singleton();
        }
        addRef();// track users

        return s_instance;
    }

    static void releaseInstance()
    {
        releasRef();

        if((0 == counter)&& (NULL !=
s_instance))
        {
            delete s_instance;
            s_instance = NULL;
        }
    }

private:
    // Make the constructor private so,
    user can not create
    //object directly but with
    GetInstance() method.
    Singleton(){
        cout<<"constructor...\n";
    }

    // don't allow users to apply delete
    on objects.
    //as we will force users to call
    destroyInstance method.

```

ANNOUNCING!!!

Quickly!

```
~Singleton(){
    cout<<"destructor...\n";
}

static void addRef(){
    ++counter;
}
static void releasRef(){
    --counter;
}

static Singleton* s_instance;
static int counter;

};

//initialize static variables here
Singleton *Singleton::s_instance = 0;
int Singleton::counter = 0;
```

Note that this question can also be asked as to provide c++ singleton destructor example. Hence, the answer should be same as above that we need to make custom design to delete instance of singleton class.

User Sneha's Question

ANNOUNCING!!!

Quickly!

Can the delete instance functionality cause infinite loop?

Author's Answer:

Before answering your question let me explain some insight of the given design in multi-threaded environment.

First, the given design is for understanding purpose and does not support multithreaded environment. In single threaded environment it does not cause any issue.

Voli Delhi - Milano

€469

ULTERIO

If you use the same code in the multi-threaded environment, following issue can occur.

ANNOUNCING!!!

OOP Concepts
with Java
Quickly!

1- inside the function `GetInstance()`, more than one thread can enter and can create more than one objects, in addition to that the function `addRef()` can be called multiple times and the value of the variable “counter” will be incremented multiple times, which is not expected.

2- In the `releaseInstance` function more than one thread can enter and execute the `releaseRef` function resulting multiple decrements of the counter variable. Which is also not expected.

So, ultimate result is that the value of the counter variable can be unpredictable and can never become ZERO in a multi-threaded environment.

If you have created hundred of objects and since, the counter is not becoming zero, the memory leak will happen. In other word, the `releaseInstance()` function will not be able to delete any instance as it will not enter the IF block.

So, coming to your question.

In multi-threaded environment if you have an application that continuously monitor the value of “counter” variable to become zero, and when the counter value becomes zero, then your application

ANNOUNCING!!!

**Get firm hold on
OOP Concepts
with Java
Quickly!**

takes some kind of action. If the value of the counter never becomes zero, obviously, your application will fall in an infinite loop.

Solution to get the design into a multi-threaded environment

To solve the problem, you can use locking an unlocking mechanism inside the GetInstance() and release instance() method. See the commented LOCK and UNLOCK.

```
static Singleton* GetInstance() {  
  
    //LOCK  
    if(NULL == s_instance) {  
  
        s_instance=new Singleton();  
    }  
  
    addRef();// track users  
  
    // UNLOCK  
  
    return s_instance;  
}  
  
static void releaseInstance() {  
  
    //LOCK  
    releasRef();  
}
```

```
        if((0 == counter)&& (NULL !=  
s_instance)) {  
  
            delete s_instance; s_instance  
= NULL;  
        }  
        //UNLOCK  
    }
```

Please look here the complete detail and code of a [Singleton class in C++ in multi-threaded environment](#).

delete instance can cause infinite loop as per my other reading is it true or not.

Thanks for the questions eshwar. No, this is not thread safe. Please consider reading [thread safe singleton class](#) here.
